Introduction

- Previous research identified the fatty acids (FAs) 15:0, 17:0, and/or 16:1 *t*9 as circulating biomarkers to represent dairy-fat intake; however, more research is needed to validate these FA biomarkers as accurate representations of dairy-fat intake.
- **Hypothesis:** The proportions of 15:0, 17:0, and 16:1 *t*9 in plasma total lipids will be greater following the consumption of 3 daily servings of full-fat yogurt compared to non-fat yogurt for 3 weeks, as will the proportion of other unique dairy-derived FAs (e.g., *aiso*-15:0, *iso*-16:0, *aiso*-17:0, 18:1 *t*11, or 18:2 *c*9, *t*11).
- **Objective 1:** Compare the plasma FA profile of individuals with prediabetes following the consumption of a diet with full-fat (3.25%) yogurt (FFY diet) or non-fat yogurt (NFY diet) to evaluate the validity of currently utilized circulating biomarkers.
- **Objective 2:** Identify additional FAs that may serve as potential biomarkers of dairy fat intake.

Methods

- Randomized, double-masked, controlled crossover pilot study
- Total of 13 participants (6 men and 7 women), aged 45-75 years
- Controlled diet intervention (8 weeks total) comparing the consumption of an experimental diet with 3 daily servings of either non-fat yogurt (30% kcal from fat) or full-fat yogurt (38% kcal from fat) for 3 weeks each (Fig. 1)
- Fasting plasma samples were taken after each diet period and analyzed for FA composition of plasma total lipids using gas-liquid chromatography

Figure 1. Overview of study design.

Figure 2. Diet-induced changes in proportions of total branched-chain FAs (A), *iso*-17:0 (B), and *aiso*-17:0 (C) in fasting plasma total lipids. Boxes represent interquartile range (25th to 75th percentile), whiskers indicate minimum and maximum values, and horizontal lines represent medians. FFY, full-fat yogurt diet. FAs, fatty acids. NFY, non-fat yogurt diet.

Results

- The proportion of total plasma branched-chain FAs, *iso*-17:0, and *aiso*-17:0 were greater in response to the FFY diet (Fig. 2), as were the proportions of *iso*-16:0 in fasting plasma ($P < 0.01$)
- No differences by diet were observed for the proportions of plasma total *trans*-FAs, total odd-chain FAs, 15:0, 17:0, 16:1 *t*9, 18:1 *t*11, *aiso*-15:0, *iso*-15:0, or 18:2 *c*9, *t*11 ($P > 0.01$)

Conclusion: Results from this pilot trial suggest that commonly utilized FA biomarkers may not be sufficiently robust to represent dairy-fat intake. Branched-chain FAs should be further explored for alternatives.
